

Design of Data Collection Programs

Outline

1. **Operations Data Needs and Availability**
2. **Farebox and Automated Fare Collection Systems (AFC)**
3. **Automatic Passenger Counter Systems (APC)**
4. **Automated Vehicle Location Systems (AVL)**
5. **Trip Time Analyzer**

Extensive + Intensive Data

Extensive: farebox

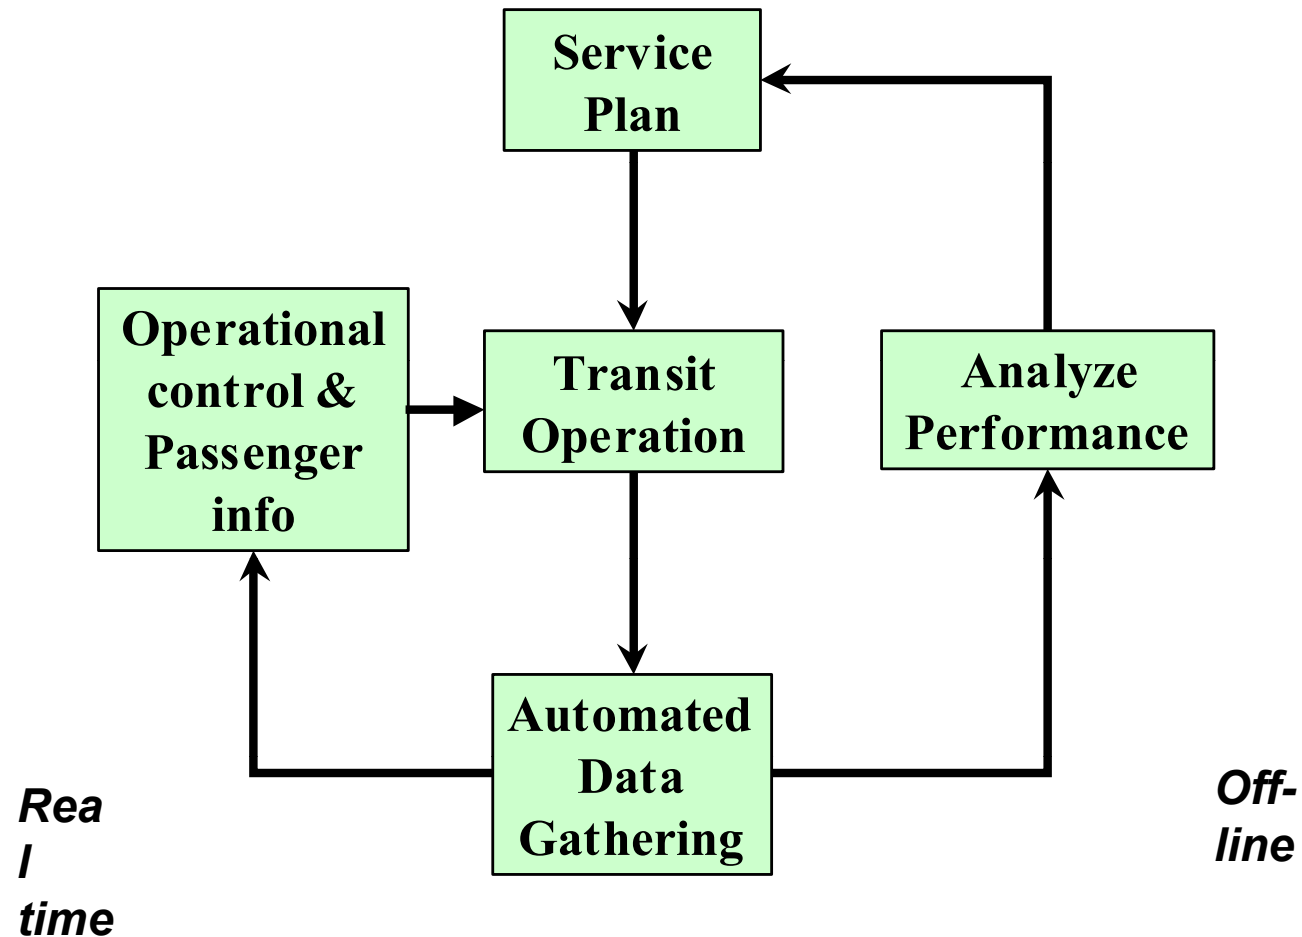

- every trip, every day (weekends, too!)
- only a rough measure of passenger activity

Intensive: ride checks, point checks, surveys

- insight on a sample of trips
- expand using farebox data
 - expand a survey by route, period
 - apply load-boardings factors found in one day's ride check

APC can be both extensive and intensive

Two Quality Loops: Real-Time and Planning

Off-Line Applications

- **Monitoring service quality (several dimensions)**
- **Schedule improvements (running times, passenger flow)**
- **Match supply to demand**
- **Analyzing Bunching Effect**
 - late causes early; early causes late
 - data on sequential buses
 - integrate operations data with passenger counts
 - operator differences
 - dwell times
 - traffic impacts (support TSP)

Traditional Farebox Data Problems

- **Operator error and inattention**
- **Poor AFC system design**
- **Poor integration between AFC and other systems**
- **Lack of management use of data**

Farebox can be your primary passenger counting tool, if ...

You invest in Hardware:

- **Card & transfer readers**
- **Link farebox to destination sign, on-board computer to segment trips, verify sign-in**
- **Transactional data**

You invest in Software:

- **Develop your own database**
- **Automate data screening, editing**
- **Integrate with schedule data, payroll, other data sources**

Farebox can be your primary passenger counting tool, if ...

You invest in Management:

- **Someone responsible to check for data quality everyday**
- **Discipline, retraining for non-performing operators**
- **Priority in maintenance & servicing**
- **Manual verification counts**

Estimating Ridership from Revenue

Traditional approach because:

Revenue is Accurate

- on sampled trips: read it now or later
- annual, systemwide (but possibly not by route)

However:

Relationship to Ridership Is Variable

- pass use, transfers, discounts, etc., distort the ridership-revenue relationship
- “average fare” surveys become out-of-date

Transactional Farebox Data Innovations

Key is the ability to record and retain a transaction for each passenger with ticket ID

Transfer and Linked Trip (O-D) Data

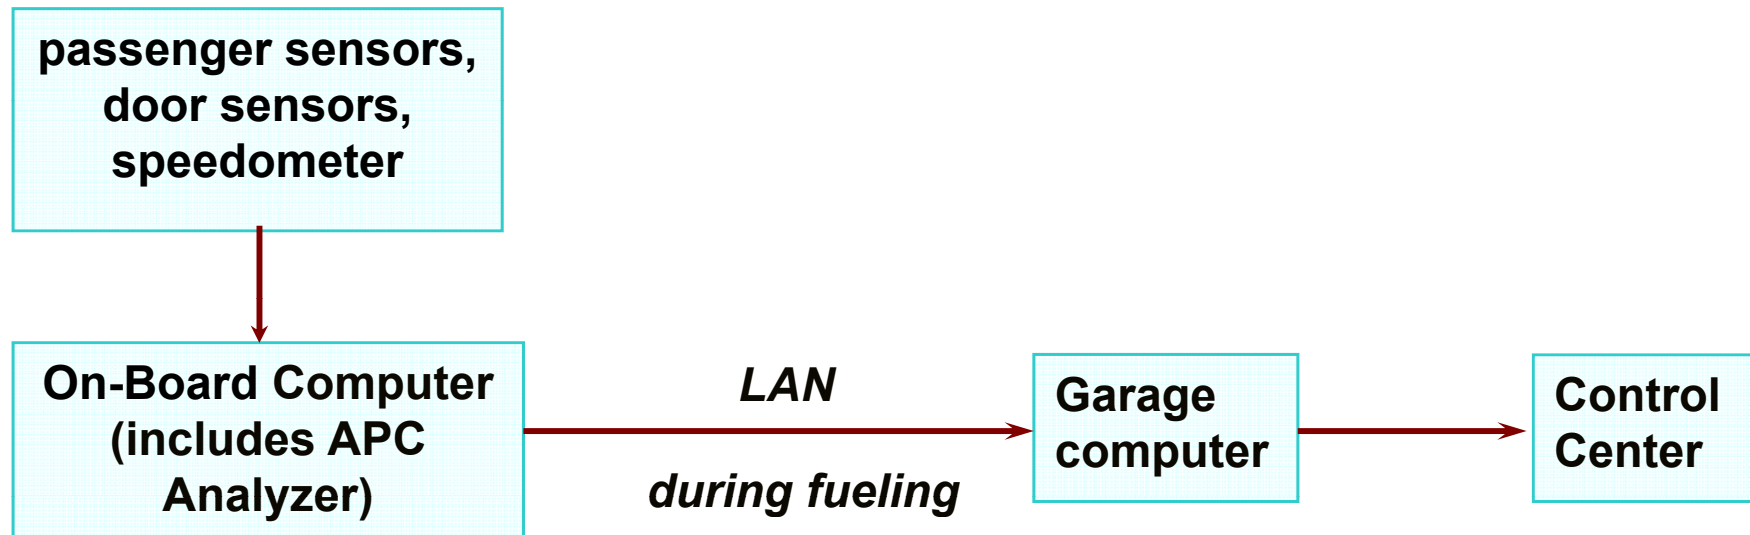

- **capture time and route of previous trip encoded on pass or transfer**
- **successful in NYC and CTA rail systems**

Estimate load, passenger-miles

- **transactional data with location stamp**
- **estimate alightings using symmetry**

Automated Data for Off-Line Application: APC Tied to on-board computer w/ nightly upload

- **APC Analyzer converts sensor signals into counts**
- **On-board computer stores one record per stop**
- **Other events may also trigger records**
- **Nightly upload can be painless**

Passenger Detection Methods

- **Breaking light beam**
 - multiple beams (high/low; inner/outer pairs)
 - sturdy mount to prevent misalignment
- **Pressure sensitive mats**
 - some designs won't work with low floor
 - footprint detection
- **Infrared (overhead)**
 - requires ambient temperature < body temperature
- **Image interpretation**

Event Records & Contents

- **Stop record**
 - time door opened, closed
 - location (GPS, odometer, etc.)
 - on count, off count
 - [maximum speed since last stop]
 - [time at crawl speed with door closed since last stop]
- **Other record types (contain time, location)**
 - speed threshold passed
 - signpost or “virtual signpost” passed
 - turn began/ended
 - periodic (e.g., 10 s)

APC - Historic Uses

- **Mimic ride check analysis**
 - **Route load profiles**
 - **Passenger-miles, NTD sampling**
 - **Running time distribution (limited)**
 - **On-time performance (limited)**

APC - Historic Deficiencies

High cost, few vendors, short-life vendors

- Usually, only 10% of the fleet gets equipped

25% to 75% data recovery

- On / off imbalance, negative loads
- Route / schedule matching problems

End-of-line issues

- Zero-out load to prevent “drift”
- End-of-line operation is often irregular, hard to match
- Ons for next trip may begin before offs from previous are finished

Equipping 10% of the Fleet ...

- **Logistical problems assigning equipped buses**
- **Not so bad for passenger count data ...**
 - Sufficient for NTD
 - Superior to any checker force
 - Adequate for conventional planning methods
- **Barely adequate for scheduling data (running time, schedule adherence)**
 - 5% effective sample - each weekday trip sampled once a month
- **Inadequate for detailed operations analysis**
- **Marginal cost of APC in integrated APC/AVL system is low**

Automated Data for Real-Time Application: AVL Tied to Radio and Central Computer

Each bus polled in turn (Wide Area Network)

Polling interval

= [unit poll time]

* [no. of buses]

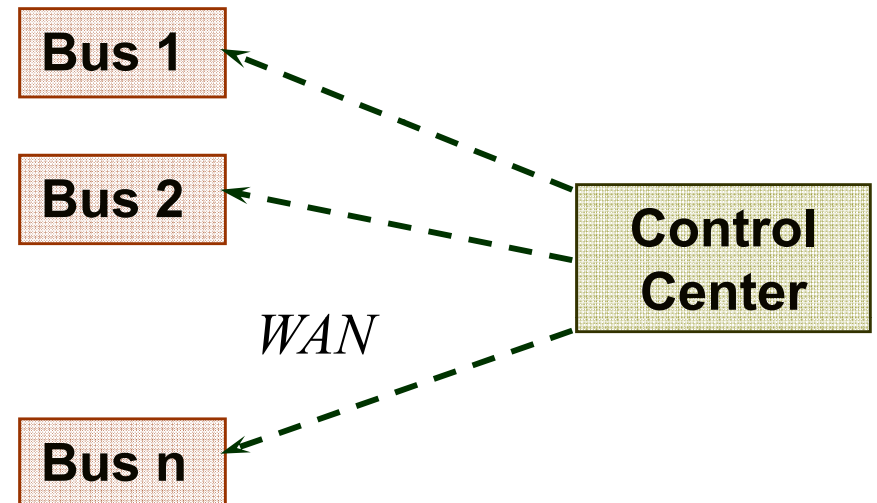

/[no. of channels]

Ex: 0.5 s per poll

* 1000 buses

/4 channels

– 125 s polling interval

Variable polling interval possible

Problem of Polling Interval

- **Analysis demands time at location;**
AVL gives location at (arbitrary) time of poll
 - interpolation errors can be significant
- **Too imprecise for efficient signal priority**
 - predict arrival time to within 5 s
 - detect exit time to within 1 s

Location Method 1: GPS

- **Interpret signals from 4+ satellites**
- **Low maintenance**
- **More \$\$ = more accuracy**
 - accurate clock
 - differential correction
- **Lose signal in tunnels canyons & tunnels**
 - re-radiate in subway tunnel
- **Reflection (“multipath”) downtown: info deteriorates where you need it most**

Other Location Methods

- **Dead reckoning**
 - key backup system to complement GPS
- **Odometer**
 - buses have electronic odometer/speedometer
 - subject to calibration error, drift
 - effective if route is known
- **Signpost (broadcasts ID)**
 - positive location; useful at key points
 - correct drift, calibrate odometer readings
 - useless off-route
 - maintenance hassle
- **Combinations of methods**

Poll Message Contents

- **Time and Location**
 - **GPS coordinates**
 - **odometer reading (in “clicks”)**
 - **ID of last signpost passed**
 - **[odometer reading when signpost was passed]**
- **ID (bus / run / route / operator)**
- **Mechanical alarms**
- **Other info: possible, but longer message slows polling rate**

AVL - Historic UsesControl Center Only

- **Security**
- **Crisis management (see big picture)**
- **Line management (limited)**
 - **What actions can dispatchers take?**
 - **Comparison to schedule often unavailable**
- **Off-line playback for incident investigations**

AVL - Historic Deficiencies

- **Data not stored for off-line analysis, except for playback (incident investigation)**
- **Often unmatched to vehicle route / schedule**
- **Always unmatched to operator schedule**

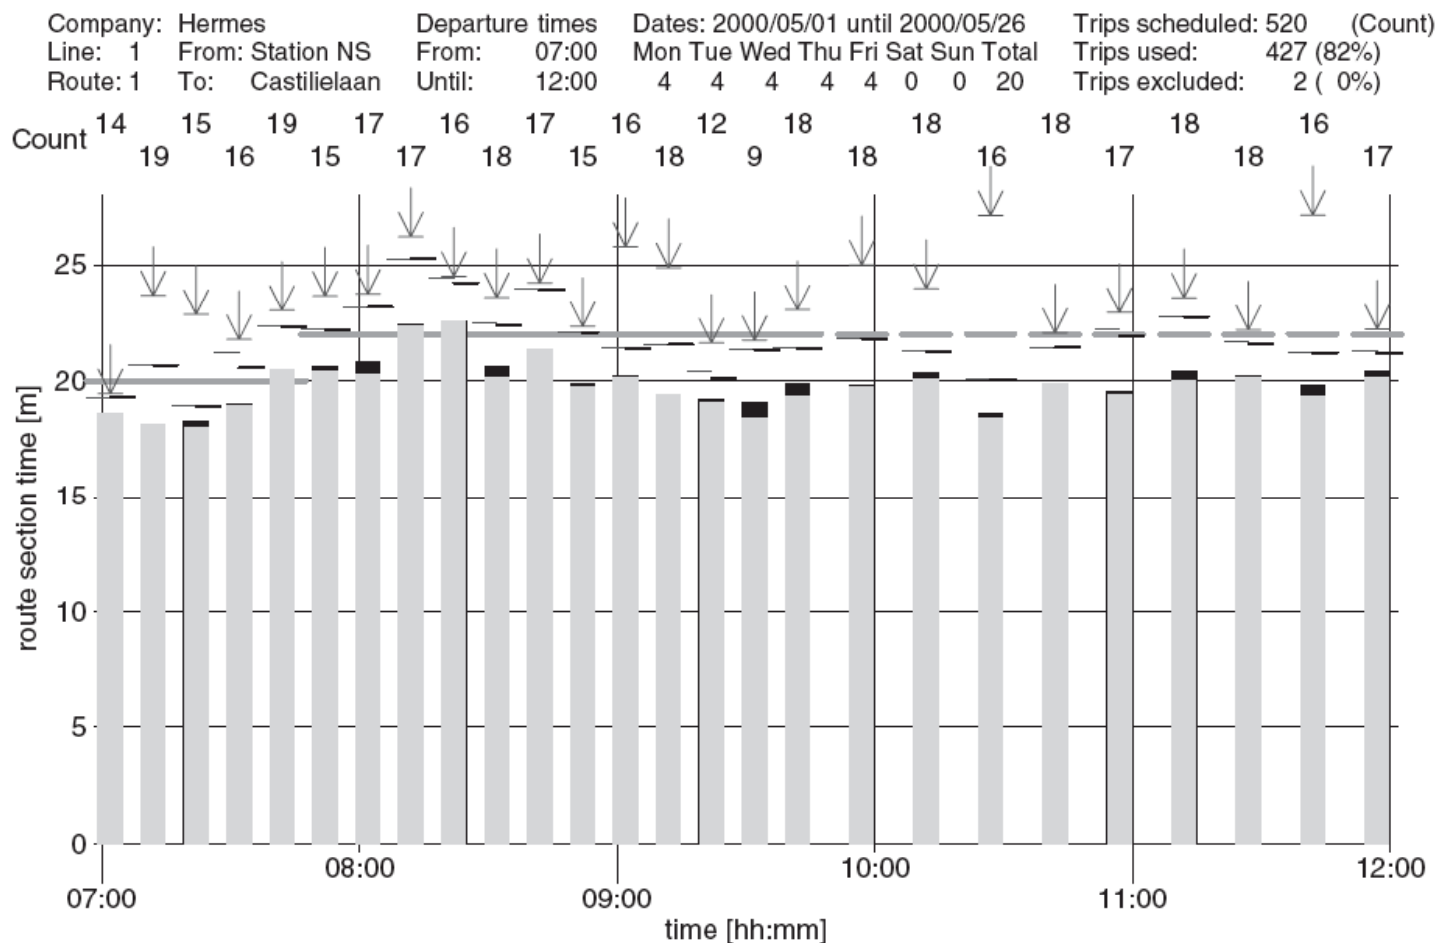

Trip Time Analyzer

**It's APC without the passenger counter;
it's AVL without the radio**

- **Record location and time in on-board computer**
- **Record events such as door open/close, speed threshold passed, etc.**
- **Permits analysis of running time, delay, schedule adherence**
- **Dutch experience: Delft University with several transit agencies**
- **Equip 100% of the fleet**

Observed Running Time by Scheduled Trip

Gross and net route section times, mean, 85% and max values

Schedule Deviation Along a Route

Individual punctuality deviations, 15%, mean and 85%

Company: USA_H28	Departure times	Dates: 2003/03/31 until 2003/04/04	Trips scheduled: 90 (Count)
Line: 1 From: Stop 1	From: 08:00	Mon Tue Wed Thu Fri Sat Sun Total	Trips used: 81 (90%)
Route: 1 To: Stop 41	Until: 11:00	1 1 1 1 1 0 0 5	Trips excluded: 0 (0%)
