---

For one-dimensional collisions, let's talk about two objects, 1 and object 2, moving with velocity  $V_1$  and another object  $V_2$  moving with velocity  $V_2$ .

Let's say they're moving on the ground.

Now I'd like to introduce the concept of relative velocity, a concept that we experience all the time in our lives.

But let's see what it actually means.

So  $V$  relative, I'm going to define this to be the velocity of  $V_1$  minus the velocity of  $V_2$ .

Now because of this minus sign that seems a little bit about abstract.

But one typical example where we see this all the time is for people traveling on highways.

You might have two cars, one car overtaking the other car.

But if you're sitting in car 1, it looks like car 2 is going quite slow.

So let's just take typical highway example.

So you might have  $V_1$ .

And we'll give it some speed.

So we'll make it 60 miles per hour.

And we'll just call this one-dimensional problem  $\hat{i}$ .

And  $V_2$ -- notice we're not speeding on a highway--  $V_2$  is going at 50 miles per hour,  $\hat{i}$ , very slow.

And the relative velocity,  $V_1$  minus  $V_2$ -- so that's what we're calling  $V$  relative-- that's 60 miles per hour minus 50 miles per hour  $\hat{i}$ .

And that's just 10 miles per hour.

And that's what people experience when one car is approaching another car.

If you're in car 2, car 1 seems like it's coming at you at 10 miles per hour.

This is what we mean by relative velocity.

There's another important example-- so that's example 1-- the other important example to look at, example 2, is

when two objects are moving in opposite directions.

So let's just see write them in terms of components this time.

So we have  $V_2 \hat{x}$ .

And we have  $V_1 \hat{x}$ .

And let's make  $V_1 \hat{x}$  positive.

So object 1 is moving in that direction.

And let's write this one as  $V_2 \hat{x}$ .

We don't have to call this initial.

We'll just call it  $V_2 \hat{x}$ .

And here  $V_2 \hat{x}$  is equal to minus  $V_1 \hat{x}$ .

So its component is negative.

And even though we drew an arrow in this picture, the picture is still fine, because if the component is negative, it means it's moving in the opposite direction.

The key arrow is the unit vector when we are writing components.

And now  $V$  relative in this case is  $V_1 \hat{x} - V_2 \hat{x}$ .

That's the  $V_1 \hat{x} - V_2 \hat{x}$ .

So there's another  $V_1 \hat{x}$ .

So the relative velocity in this case has a component that's twice the speed of  $V_1$ .

If two objects are moving together at the same speed, the relative velocity, the way we've defined it, has twice the magnitude of either velocity.

And this is an important example to consider in collisions.

Now this relative velocity concept we'll see we'll add a new way of thinking about elastic collisions with no external forces in one dimension.
